SEEQ®
Technology, Incorporated

28C64
Timer E²
64K Electrically Erasable PROM

July 1991

Features

- **Military, Extended and Commercial Temperature Range**
  - –55°C to +125°C Operation (Military)
  - –40°C to +85°C Operation (Extended)
  - 0°C to +70°C Operation (Commercial)
- **CMOS Technology**
- **Low Power**
  - 50 mA Active
  - 200 µA Standby
- **Page Write Mode**
  - 64 Byte Page
  - 160 us Average Byte Write Time
- **Byte Write Mode**
- **Write Cycle Completion Indication**
  - $\overline{DATA}$ Polling
- **On-Chip Timer**
  - Automatic Erase Before Write
- **High Endurance**
  - 10,000 Cycles/Byte Minimum
  - 10 Year Data Retention
- **Power Up/Down Protection Circuitry**
- **200 ns Maximum Access Time**
- **JEDEC Approved Byte Wide Pinout**
- **MIL 883 Class B Complaint**
  MIL SMD 5962 Complaint

Description

SEEQ's 28C64 is a CMOS 5V only, 8K x 8 Electrically Erasable Programmable Read Only Memory (EEPROM). It is manufactured using SEEQ's advanced 1.25 micron

Note: The PLCC has the same pin configuration as the LCC except pins 1 and 17 are don't connects.

Pin Names

A_0-A_5	ADDRESSES—COLUMN
A_6-A_{12}	ADDRESSES—ROW
$\overline{CE}$	CHIP ENABLE
$\overline{OE}$	OUTPUT ENABLE
$\overline{WE}$	WRITE ENABLE
I/O_{0-7}	DATA INPUT (WRITE)/DATA OUTPUT (READ)
NC	NO CONNECTION

Q Cell is a trademark of SEEQ Technology, Inc.

CMOS Process and is available in most Thru Hole and Surface Mount Package options as listed under "Ordering Information." The 28C64 is ideal for applications which require low power consumption, non-volatility and in system reprogrammability. The endurance, the number of times a byte can be written, is specified at 10,000 cycles per byte and, is typically 1,000,000 cycles per byte. The extraordinary high endurance was accomplished using SEEQ's proprietary oxynitride EEPROM process and it's innovative Q Cell™ design. System reliability, in all applications, is higher because of the low failure rate of the Q Cell.

The 28C64 has an internal timer which automatically times out the write time. The on-chip timer, along with input latches free the microprocessor for other tasks while the part is busy writing. The 28C64's write cycle time is 10 ms. An automatic erase is performed before a write. The $\overline{DATA}$ polling feature of the 28C64 can be used to determine the end of a write cycle. Once the write cycle has been completed, data can be read in a maximum of 200 ns. Data retention is specified for 10 years.

Device Operation

Operational Modes

There are five operational modes (see Table1) and, except for the chip erase mode, only TTL inputs are required. A Write can only be initiated under the conditions shown. Any other conditions for $\overline{CE}$, $\overline{OE}$, and $\overline{WE}$ will inhibit writing and the I/O lines will either be in a high impedance state or have data, depending on the state of aforementioned three input lines.

Mode Selection

Mode	$\overline{CE}$	$\overline{OE}$	$\overline{WE}$	I/O
Read	V_{IL}	V_{IL}	V_{IH}	D_{OUT}
Standby	V_{IH}	X	X	High Z
Write	V_{IL}	V_{IH}	V_{IL}	D_{IN}
Write	X	V_{IL}	X	High Z/D_{OUT}
Inhibit	X	X	V_{IH}	High Z/D_{OUT}
Chip Erase	V_{IL}	V_H	V_{IL}	X

X: Any TTL level
V_H: High Voltage

Reads

A read is accomplished by presenting the address of the desired byte to the address inputs. Once the address is stable, $\overline{CE}$ is brought to a TTL low in order to enable the chip. The $\overline{WE}$ pin must be at a TTL high during the entire read cycle. The output drivers are made active by bringing Output Enable ($\overline{OE}$) to a TTL low. During read, the address, $\overline{CE}$,$\overline{OE}$, and I/O latches are transparent.

Writes

To write into a particular location, the address must be valid and a TTL low applied to the Write Enable ($\overline{WE}$) pin of a selected ($\overline{CE}$ low) device. This combined with Output Enable ($\overline{OE}$) being high, initiates a write cycle. During a write cycle, all inputs except data are latched on the falling edge of $\overline{WE}$ or $\overline{CE}$, whichever occurred last. Write enable needs to be at a TTL low only for the specified t_{WP} time. Data is latched on the rising edge of $\overline{WE}$ or $\overline{CE}$whichever occurred first. An automatic erase is performed before data is written.

Write Cycle Control Pins

For system design simplification, the 28C64 is designed such that either the $\overline{CE}$ or $\overline{WE}$ pin can be used to initiate a write cycle. The device uses the latest high-to-low transition of either $\overline{CE}$ or $\overline{WE}$ signal to latch addresses and the earliest low-to-high transition to latch the data. Address and $\overline{OE}$ setup and hold are with respect to the later of $\overline{CE}$ or $\overline{WE}$; data setup and hold is with respect to the earlier of $\overline{WE}$ or $\overline{CE}$.

To simplify the following discussion, the $\overline{WE}$ pin is used as the write cycle control pin throughout the rest of this data sheet. Timing diagrams of both write cycles are included in the AC Characteristics.

Write Mode

One to 64 bytes of data can be randomly loaded into the page. The part latches row addresses, A6-A12, during the first byte write. These addresses are latched on the falling edge of the $\overline{WE}$ signal and are ignored after that until the end of the write cycle. This will eliminate any false write into another page if different row addresses are applied and the page boundary is crossed.

The column addresses, A0-A5, which are used to select different locations of the page, are latched every time a new write is initiated. These addresses and the $\overline{OE}$ state (high) are latched on the falling edge of $\overline{WE}$ signal. For proper write initiation and latching, the $\overline{WE}$ pin has to stay low for a minimum of t_{WP} ns. Data is latched on the rising edge of $\overline{WE}$, allowing easy microprocessor interface.

Upon a low to high $\overline{WE}$ transition, the 28C64 latches data and starts the internal page load timer, The timer is reset on the falling edge of the $\overline{WE}$ signal if another write is initiated before the timer has timed out. The timer stays

reset while the $\overline{WE}$ pin is kept low. If no additional write cycles have been initiated within t_{BLC} after the last $\overline{WE}$ low to high transition, the part terminates the page load cycle and starts the internal write. During this time which takes a maximum of 10 ms, the device ignores any additional write attempts. The part can be read to determine the end of write cycle ($\overline{DATA}$ polling).

Extended Page Load

In order to take advantage of the page mode's faster average byte write time, data must be loaded at the page load cycle time (t_{BLC}). Since some applications may not be able to sustain transfers at this minimum rate, the 28C64 permits an extended page load cycle. To do this, the write cycle must be "stretched" by maintaining $\overline{WE}$ low, assuming a write enable-controlled cycle, and leaving all other control inputs ($\overline{CE}$, $\overline{OE}$) in the proper page load cycle state. Since the page load timer is reset on the falling edge of $\overline{WE}$, keeping this signal low will not start the page load timer. When $\overline{WE}$ returns high, the input data is latched and the page load cycle timer begins. In $\overline{CE}$ controlled write the same is true, with $\overline{CE}$ holding the timer reset instead of $\overline{WE}$.

$\overline{DATA}$ Polling

The 28C64 has a maximum write cycle time of 10 ms. Typically though, a write will be completed in less than the specified maximum cycle time. $\overline{DATA}$ polling is a method of minimizing write times by determining the actual end-point of a write cycle. If a read is performed to any address while the 28C64 is **still writing**, the device will present the ones-complement of the last byte written. When the 28C64 has **completed** its write cycle, a read from the last address written will result in valid data. Thus, software can simply read from the part until the last data byte written is read correctly.

A $\overline{DATA}$ polling read can occur immediately after a byte is loaded into a page, prior to the initation of the internal write cycle. $\overline{DATA}$ polling attempted during the middle of a page load cycle will present a ones complement of the most recent data byte loaded into the page. Timing for a $\overline{DATA}$ polling read is the same as a normal read.

Chip Erase

Certain applications may require all bytes to be erased simultaneously. This feature, which requires high voltage, is optional and timing specifications are available from SEEQ.

Power Up/Down Considerations

There is internal circuitry to minimize a false write during power up or power down. This circuitry prevents writing under any one of the following conditions.

1. V_{CC} is less than $V_{WI}V$.
2. A high to low Write Enable ($\overline{WE}$) transition has not occurred when the V_{CC} supply is between $V_{WI}V$ and V_{CC} with $\overline{CE}$ low and $\overline{OE}$ high.

Writing will also be inhibited when $\overline{WE}$, $\overline{CE}$, or $\overline{OE}$ are in TTL logical states other than that specified for a write in the Mode Selection table.

Absolute Maximum Stress Ratings*

Temperature
Storage ..... −65°C to +150°C
Under Bias
Military/Extended Temperature .. −65°C to +135°C
Commercial Temperature ..... −10°C to +80°C

D.C. Voltage applied to all Inputs or Outputs with respect to ground ..... +6.0 V to −0.5 V
Undershoot pulse of less than 10 ns (measured at 50% point) applied to all inputs or outputs with respect to ground ..... −1.0 V

Overshoot pulse of less than 10 ns (measured at 50% point)applied to all inputs or outputs with respect to ground ..... + 7.0 V

**COMMENT: Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*

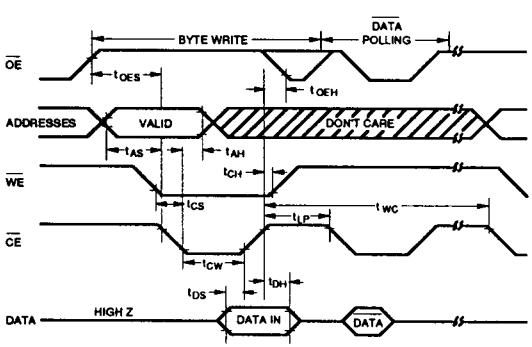
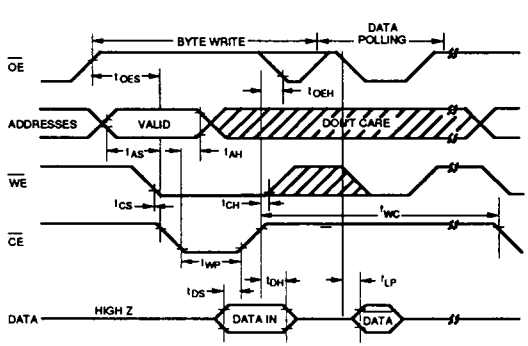
Write Timing

$\overline{WE}$ CONTROLLED WRITE CYCLE



$\overline{CE}$ CONTROLLED WRITE CYCLE



NOTES:

1 Address hold time is with respect to the falling edge of the control signal $\overline{WE}$ or $\overline{CE}$.

2. $\overline{WE}$ and $\overline{CE}$ are noise protected. Less than a 20 nsec write pulse will not activate a write cycle.

3. t_{BLC} min. is the minimum time before the next byte can be loaded. t_{BLC} max. is the minimum time the byte load timer waits before initiating internal write cycle.
